Introduction (2/6)

Is it possible to start in A, cross over each bridge exactly once, and end up back in A?

Introduction (1/6)

The premise of Graphs : the bridges of Königsberg : Euler 1736

- Leonard Euler Visited Königsberg
- People wondered whether it is possible to take a walk, end up where you started from, and cross each bridge in Königsberg exactly once
- Generally it was believed to be impossible

Introduction (4/6)

Graph modeling : Bridges are **edges**.

Introduction (5/6)

Is there a “walk” starting at A and ending at A and passing through each edge exactly once?

Introduction (6/6)

Such a walk is called an **eulerian cycle**. Solving this problem will be discussed later.
Any intuition?

Graph ?

(a) A graph (to most of the world)

(b) A graph (in algorithms)

Two flavors of graphs : **directed** and **undirected**.

Basic definitions and Terminology

- **Undirected graph** $G = (V, E)$
- V set of **vertices**
- E set of **edges** between unordered pairs of vertices called endpoints
- Captures pairwise relationship between objects
- Graph size parameters : $n = |V|$ (number of vertices), $m = |E|$ (number of edges).

Example

Nodes : $V = \{1, 2, 3, 4, 5\}$, $n = 5$

Edges : $S = \{\{1, 2\}, \{1, 3\}, \{2, 3\}, \{3, 4\}, \{2, 4\}, \{2, 5\}\}$, $m = 6$

Basic definitions and Terminology

- **Directed graph** $G = (V, E)$
- V set of **vertices**
- E set of **arcs** between ordered pairs of vertices
- Captures oriented relationship between objects
- Graph size parameters : $n = |V|$ (number of vertices), $m = |E|$ (number of arcs).

Example

Nodes : $V = \{1, 2, 3, 4, 5\}$, $n = 5$

Arcs : $S = \{(1, 2), (1, 3), (3, 2), (3, 4), (2, 4), (5, 2)\}$, $m = 6$

Some examples of graphs

- Communication networks : collection of computers connected via a network, vertices \equiv computers, edges \equiv peering relationships
- Wireless networks : vertices \equiv devices in physical location, edges \equiv signal reception
- Information networks : Web graph, vertices \equiv web pages, arcs \equiv hyperlinks
- Social networks : vertices \equiv people, edges \equiv friend relationship
- Transportation networks : map of routes served by an airline carrier, vertices \equiv airports, edges \equiv non-stop flight

Definitions (directed graphs)

- **Tails and Heads** : A (directed) arc (i, j) has two endpoints i and j : i is the **tail** of the arc and j is its **head**.
The arc (i, j) emanates from node i and terminates at node j . An arc (i, j) is incident to vertices i and j . The arc (i, j) is an outgoing arc of node i and an incoming arc of node j .
- **Degrees** : The **indegree** $d^-(i)$ of a node i is the number of incoming arcs of node i and its **outdegree** $d^+(i)$ is the number of its outgoing arcs. The **degree** $d(i)$ of a node i is the sum of its indegree and outdegree, $d(i) = d^+(i) + d^-(i)$.

Property

The sum of indegrees of all vertices equals the sum of outdegrees of all vertices and both are equal to the number of arcs m :

$$\sum_{i \in V} d^+(i) = \sum_{i \in V} d^-(i) = m$$
$$\sum_{i \in V} d(i) = 2m$$

Illustration

Example

Graph : $n = 5, m = 6$

Degrees :

i	1	2	3	4	5	\sum_i
d^+	2	1	2	0	1	$6 = m$
d^-	0	3	1	2	0	$6 = m$
d	2	4	3	2	1	$12 = 2m$

Navigation icons

Illustration

Example

Graph : $n = 5, m = 6$

Degrees :

i	1	2	3	4	5	\sum_i
d	2	4	3	2	1	$12 = 2m$

Navigation icons

Definitions (undirected graphs)

The definitions for directed graphs easily translate into those for undirected networks.

- The vertices i and j are **adjacent** for an edge $\{i, j\}$.
- Degree : The **degree** $d(i)$ of a node i is the sum of its adjacent vertices.

Property

$$\sum_{i \in V} d(i) = 2m$$

Navigation icons

Paths and Cycles

- A **path** in an undirected graph $G = (V, E)$ is a sequence P of vertices $v_1, v_2, \dots, v_{k-1}, v_k$ with the property that each consecutive pair v_i, v_{i+1} is joined by an edge in E .
- A path is **simple** if all vertices are distinct.
- A **cycle** is a path $v_1, v_2, \dots, v_{k-1}, v_k$ in which $v_1 = v_k$, $k > 2$, and the first $k - 1$ vertices are all distinct.

Example (Cycle)

Cycle : $C = (1, 2, 4, 5, 3, 1)$

Navigation icons

Graph Connectivity

- An undirected graph $G = (V, E)$ naturally falls into “pieces”, which are called **connected components**.
- More formally, a connected component is a maximal subset $S \subseteq V$ of vertices such that there is a path from any vertex in S to any other vertex in S .

Example

Connected components : $\{1, 3, 5, 7, 9\}$, $\{2, 4\}$, and $\{6, 8, 10\}$

Navigation icons

Trees

An undirected graph is a **tree** if it is connected and does not contain a cycle.

Property

Let G be an undirected graph on n vertices. Any two of the following statements imply the third.

- G is connected.
- G does not contain a cycle.
- G has $n - 1$ edges.

Navigation icons

Rooted Trees

Given a tree T , choose a root node r and orient each edge away from r . Models hierarchical structure.

a tree

the same tree, rooted at 1

Navigation icons

Measuring the Size of a Graph

- Number of edges in a graph

Example (Quizz)

Consider an undirected graph with n vertices and no parallel edges. Assume that the graph is connected. What are the minimum and maximum numbers of edges, respectively, that the graph could have?

- Sparse vs. Dense Graphs
A graph is sparse if the number of edges is relatively close to linear in the number of vertices, and dense if this number is closer to quadratic in the number of vertices.

Navigation icons

Representing a Graph (1/2)

Adjacency List

- ▶ An array containing the graph's vertices.
- ▶ For each vertex, a pointer to each of the incident edges.

Example (Quizz)

How much space does the adjacency list representation of a graph require, as a function of the number n of vertices and the number m of edges?

Representing a Graph (2/2)

Adjacency Matrix

- ▶ square $n \times n$ matrix A (equivalently a two-dimensional array,) with only zeroes and ones as entries. Each entry A_{ij} is defined as :

$$A_{ij} = \begin{cases} 1 & \text{if } (i, j) \text{ belongs to } E, \\ 0 & \text{otherwise.} \end{cases}$$

$$\begin{matrix} & \begin{matrix} 1 & 2 & 3 & 4 \end{matrix} \\ \begin{matrix} 1 \\ 2 \\ 3 \\ 4 \end{matrix} & \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 \end{pmatrix} \end{matrix}$$

Example (Quizz)

How much space does the adjacency matrix representation of a graph require, as a function of the number n of vertices and the number m of edges?

Comparing the representation

It depends...

- on the **density** of the graph, i.e. on how the number m of edges compares to the number n of vertices.
- on which **operations** you want to support.

Example (Quizz)

- How many operations are required to identify if a vertex u is adjacent to a vertex v ?
- How many operations are required to identify the incoming edges of a vertex v ?
